Preventing malnutrition in all its forms

Globally, there were **155 million**  children under 5 years of age stunted, 52 million wasted and 41 million overweight¹

In low and middle income countries, infants 0-5 months of age who are not breastfed have a **14 times**  higher risk of death compared to those who are exclusively breastfed.³

It is estimated that breastfeeding reduces the risk of overweight and obesity by about **10%**  compared to formula feeding²

More than **1.9 billion**  adults (18 years and older) were overweight. Of these, over 650 million were obese¹

Lifelong positive health effects of optimal breastfeeding

There is strong evidence that optimal breastfeeding has many effects on:

- Mother: helps with birth spacing, reduces risk of breast and ovarian cancers, and lowers the risk of hypertension.
- Child: combats infectious diseases, decreases incidence and severity of diarrhoea, lowers respiratory infections and acute otitis media, prevents dental caries and malocclusion, and increases intelligence.
